### **Abstract:**

In this work, nickel (Ni) substituted zinc ferrite nanoparticles (NPs) with formula  $\text{Ni}_x\text{Zn}_{1-x}\text{Fe}_2\text{O}_4$  ( $x = 0, 0.1, 0.3, 0.4$ ) were synthesized using a microwave-assisted hydrothermal method. We further evaluated the effects of Ni substitution on structural, defects, magnetic and gas sensing properties of the pure  $\text{ZnFe}_2\text{O}_4$  arising from the nickel substitution. The gas sensing findings revealed that the sensor based on 0.1 Ni substituted  $\text{ZnFe}_2\text{O}_4$  displayed a high response of 34.5–40 ppm of acetone at an optimal working temperature of 120 °C. All sensors demonstrated an excellent response towards acetone and remarkable selectivity against  $\text{NO}_2$ ,  $\text{NH}_3$ ,  $\text{CH}_4$ , and  $\text{CO}$  with the sensor based on  $\text{Ni}_{0.1}\text{Zn}_{0.9}\text{Fe}_2\text{O}_4$  displaying the best response as compared to the rest. The enhanced sensing capability of the  $\text{Ni}_{0.1}\text{Zn}_{0.9}\text{Fe}_2\text{O}_4$  based sensor stems from combined effects of high concentration of surface defects and  $\text{Fe}^{2+}$  cations in the octahedral sites which promoted greater adsorption of oxygen species and adsorption capacity. The gas sensing mechanism of the  $\text{Ni}_{0.1}\text{Zn}_{0.9}\text{Fe}_2\text{O}_4$  sensor was therefore explained in consideration of a higher surface reaction which occurs at its surface due to higher adsorbed oxygen molecules serving as direct adsorption sites for oxygen and acetone.
